Table of Contents:

Step 1: Database Backend Overview	2
Step 2: ER and UML Diagrams	4
Step 3: Normalization to 3NF	6
Step 4: Boyce-Codd NF Justification	8
Step 5: Table Implementation	9
Step 6: Populate Database with Data	11
Step 7: Run 5 Useful SQL Queries	12
Step 8: Optimize for Scale and Efficiency	13
Step 9: CSV Export Script	14

Step 1:

Think of a practical application to a database backend, you may research this portion and provide citations within your report. Your proposed application must need a complicated database with at least six tables. Provide a two to three paragraph description of this application. A great example would be an inventory management system backend for a company with multiple products

Massive Multiplayer Online games, (MMO), are games where thousands to millions of players all login and play the same game together in the same session. As such, the computational power required to run these games is absolutely massive and the amount of data that is stored between item, ability, and player information is also on a massive scale.

Blizzard, developer of arguably the world's most popular MMO, "World of Warcraft", (WOW), released a dev post regarding the change from an older version of world of warcraft to a more recent version, and the difficulty in reverting to previous version of WOW. In the blog post they detailed some of the underlying changes that occurred when the switch was made to go to the newer version, including how they would update their database system in order to reduce the space that is "taken up by nothing". They achieved this by normalizing their databases from update to update and eventually reached the point where they are today, which also makes it impossible to go backwards and run a previous version of WOW on their current servers because of how fundamentally different the data is stored.

<https://worldofwarcraft.com/en-us/news/21881587>

This article posted by Blizzard gives us some insight into how an MMO would store information in a database, and so we thought it would be an interesting idea to create a database system for an MMO. The system that we are developing the backend for is an MMO and we have tables that store all of the basic information required to host and store data for a given fantasy MMO.

We decided that for our project we would attempt to create a system that would attempt to solve the issue of storing tables of data for the calculation of damage and positioning for an online MMO. As well as recording the current state of a character to be reloaded in a future session playing the game.

The tables are as follows:

Account { Username, Email, Password, pID, DOB, Name }

- Allows them to login to the character associated with the account

Player { pID, Name, Class, Level, XP, Health, Mana, Gold, Ability, Item1, Item2 }

- Limited to 2 items and 1 ability
- Allows for data about character customization as well as player levelling progress
- Character's experience is reset to zero when the character gains a level
- Has stats like Health and Mana for real time gameplay
- Allows us to store and remember the state the given character is

Class { Class, Level, Str, Agi, Int, Attack, Defense }

- Stores information about a given class' base stats at a given level
- Stats in this table provide the base stats of a given character
Ex 'Str' of 10 increases an associated character 100 'Health'

Monster { mID, Name, Description, Attack, Defense, Bounty, Health, Mana, Ability }

- Limited to 1 ability and no items
- Records combat stats for reference in gameplay
- Has stats like Health and Mana for real time gameplay
- Bounty gives the character that slayed the monster that amount of gold and xp. Ex bounty of 10 grants 10 'Gold' AND 10 'XP' on kill

Item { iID, Name, Description, Attack, Defence, Level }

- Provides additional stats that affect a characters stats

Ability { abID, Name, Description, Attack, Mgc, MgcStr, Level }

- 'Mgc' is a string that refers to an already known effect, and the 'MgcStr' has the damage or effect of that ability.
Ex 'Mgc' of ice, and 'MgcStr' of 10 does 10 ice damage.

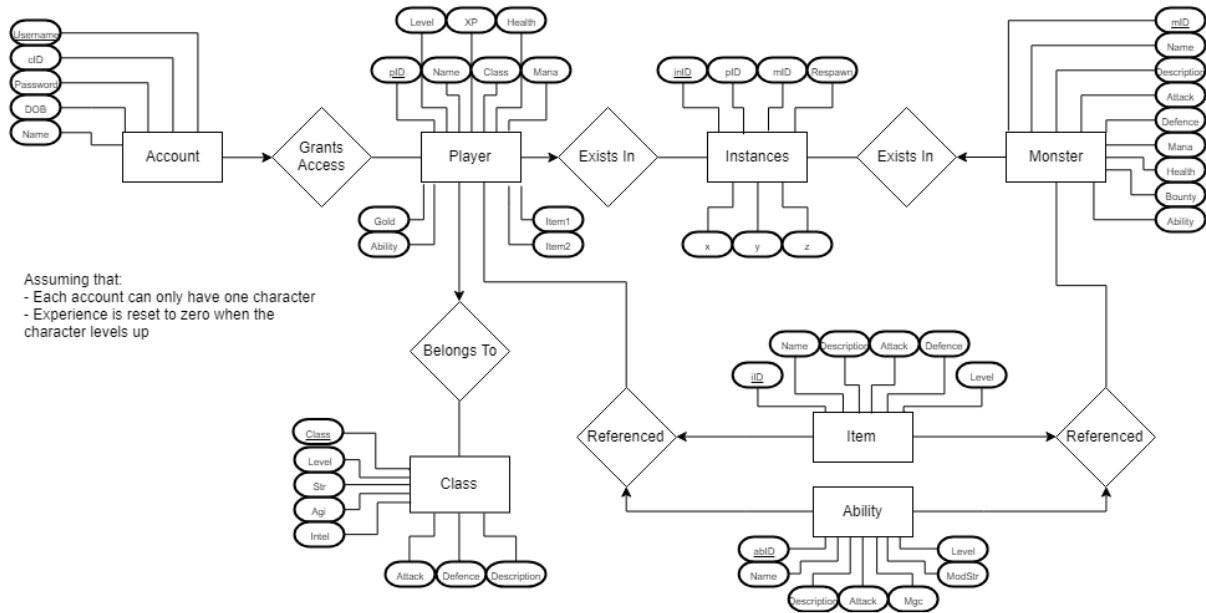

Instances { inID, pID, mID, x, y, z, Respawn }

- Vital to know which characters/monsters to render for every player, acts as a global reference for every players client to know what to render and where
- Monsters and Characters are assigned an 'inID' when they are initialized
- They are then placed into this table to keep track of their 'x', 'y', 'z' coordinates
- As well as a respawn timer if they are dead, to know when they will revive
- The 'cID' and 'mID' fields will be populated with their respective ID, and null otherwise
- When a user logs out of the game their tuple is removed from the table which also means that their character won't be rendered
- The Instances table flushes (removes all entries and repopulates) every 100,000 instance to ensure that the 'inID' value doesn't get too large

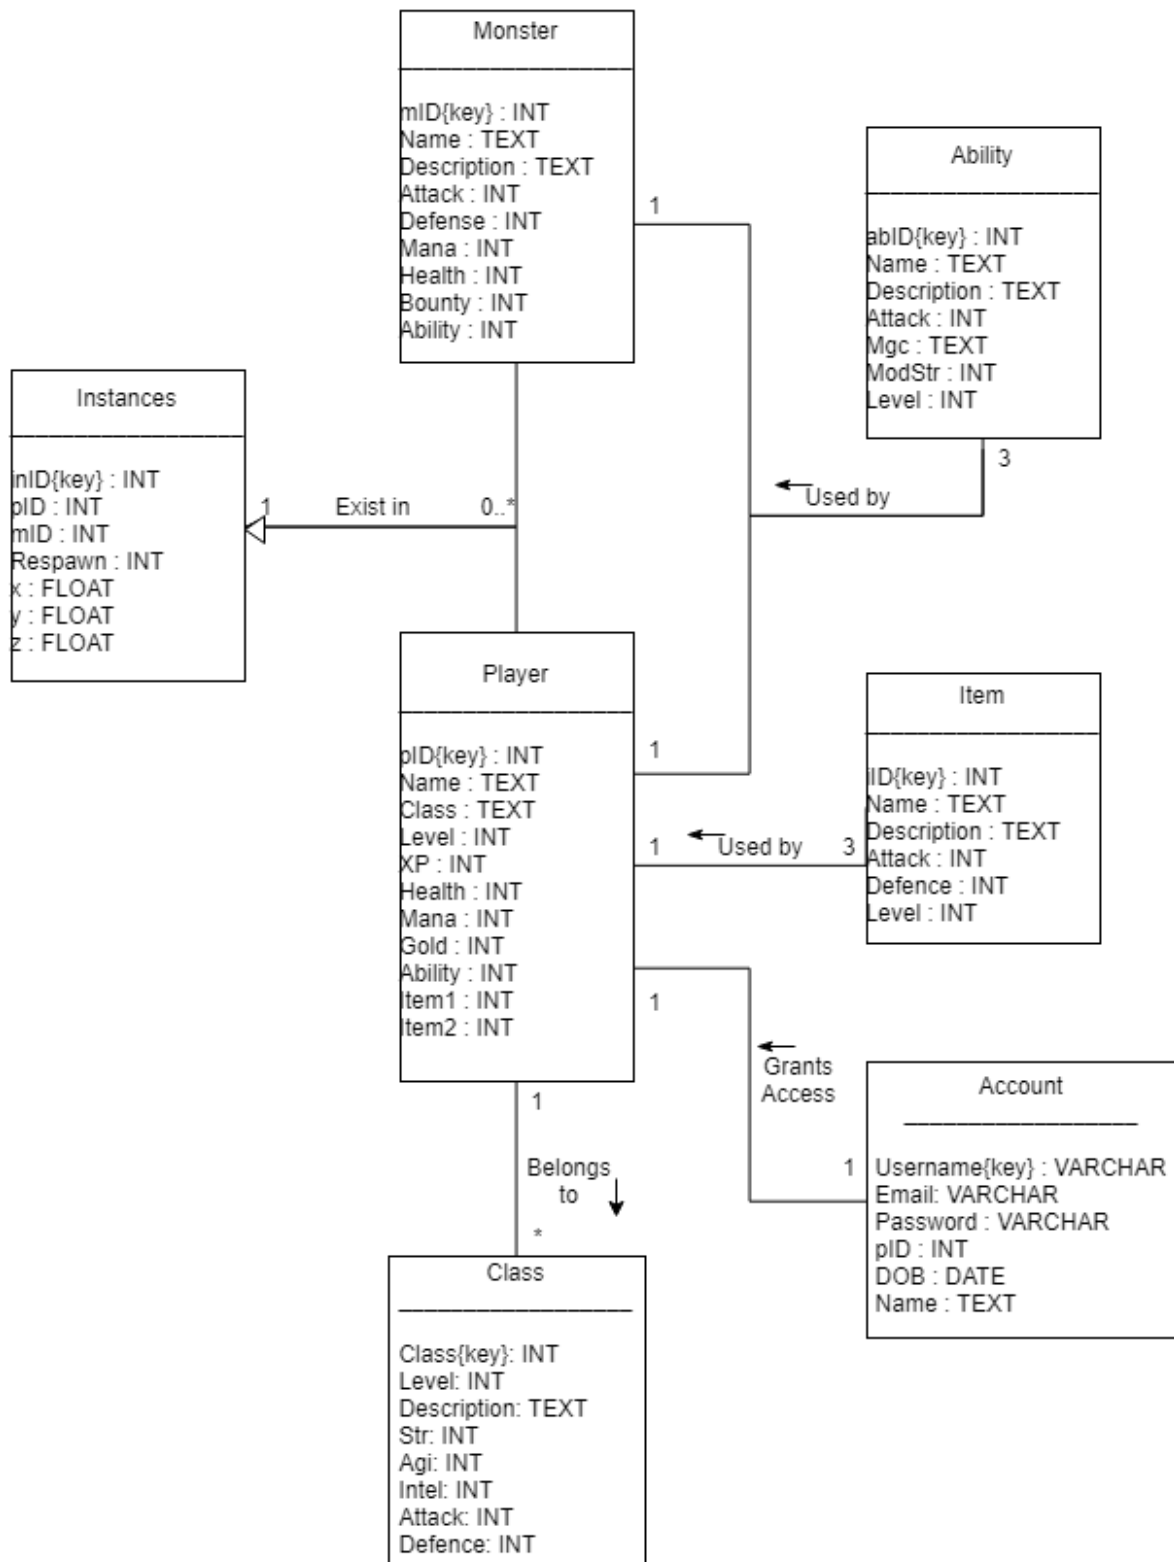

Step 2:

Design the database utilizing an ER diagram (or several if it makes sense to do so), following by that create the UML class diagram for that database. Please include your diagram within your report.

ER Diagram:

UML Diagram:

Step 3:

Analyze the database for performance and redundancy (this means you need to ensure your database is in 3NF). Include the analysis within your report. If it does not make sense to go all the way up to 3NF justify why.

Account { Username, Email, Password, cID, DOB, Name }

- 1NF: Rows are uniquely identified
Each cell only has 1 value
- 2NF: Is in 1NF
Each non-key attribute relies fully on the primary key value
- 3NF: Is in 2NF
No transitive dependency
No derived data

Character { cID, Name, Class, Level, XP, Health, Mana, Gold, Ability, Item1, Item2 }

- 1NF: Rows are uniquely identified
Each cell only has 1 value
- 2NF: Is in 1NF
Each non-key attribute relies fully on the primary key value
- 3NF: Is in 2NF
No transitive dependency
No derived data

Class { Class, Level, Str, Agi, Intel, Attack, Defense }

- 1NF: Rows are uniquely identified
Each cell only has 1 value
- 2NF: Is in 1NF
Each non-key attribute relies fully on the primary key value
- 3NF: Is in 2NF
No transitive dependency
No derived data

Monster { mID, Name, Description, Attack, Defense, Bounty, Level, Health, Mana, Ability }

- 1NF: Rows are uniquely identified
Each cell only has 1 value
- 2NF: Is in 1NF
Each non-key attribute relies fully on the primary key value
- 3NF: Is in 2NF
No transitive dependency
No derived data

Item { iID, Name, Description, Attack, Defense, Level }

- 1NF: Rows are uniquely identified
Each cell only has 1 value
- 2NF: Is in 1NF
Each non-key attribute relies fully on the primary key value
- 3NF: Is in 2NF
No transitive dependency
No derived data

Ability { abID, Name, Description, Attack, Mgc, MgcStr, Level }

- 1NF: Rows are uniquely identified
Each cell only has 1 value
- 2NF: Is in 1NF
Each non-key attribute relies fully on the primary key value
- 3NF: Is in 2NF
No transitive dependency
No derived data

Instances { inID, cID, mID, x, y, z, Respawn }

- 1NF: Rows are uniquely identified
Each cell only has 1 value
- 2NF: Is in 1NF
Each non-key attribute relies fully on the primary key value
- 3NF: Is in 2NF
No transitive dependency
No derived data

Every table meets requirements to be in 3NF

Step 4:

Analyze whether or not the database is in Boyce–Codd normal form, if it is not then why not? Would you benefit from the database being in Boyce-Codd normal form? Justify your answer. Include this within your report.

Given that there are no tables that include functional dependencies and that the tables are all already in 3NF, our database is in Boyce-Codd normal form.

Boyce-Codd normal form can essentially be boiled down to a schema being in 3NF and not having any overlapping candidate keys. Because each attribute represented in our tables has no dependency on any key other than the primary key, we can assume that there are no overlapping candidate keys, and then we already know the table is already in 3NF. So it is in BCNF

Step 5:

Implement the database. Include the code within your report (with screenshots if applicable).

```
CREATE DATABASE Project;
```

```
CREATE TABLE account (  
    Username varchar(255),  
    Email varchar(255) NOT NULL,  
    Password varchar(255) NOT NULL,  
    pID INT NOT NULL,  
    DOB DATE NOT NULL,  
    Name TEXT NOT NULL,  
    UNIQUE (Username, Email, pID),  
    PRIMARY KEY (Username));
```

```
CREATE TABLE player (  
    pID INT(11) NOT NULL AUTO_INCREMENT,  
    Name TEXT,  
    Class TEXT,  
    Level INT DEFAULT 0,  
    XP INT,  
    Health INT,  
    Mana INT,  
    Gold INT,  
    Ability INT,  
    Item1 INT,  
    Item2 INT,  
    UNIQUE (pID),  
    PRIMARY KEY (pID));
```

```
CREATE TABLE Class (  
    Class INT(11) NOT NULL AUTO_INCREMENT,  
    Description TEXT,  
    Level INT,  
    Str INT,  
    Agi INT,  
    Intel INT,  
    Attack INT,  
    Defence INT,  
    UNIQUE (Class),  
    PRIMARY KEY (Class));
```

```
CREATE TABLE Monster (  
  AUTO_INCREMENT,
```

```
  mID INT(11) NOT NULL
```

```
  Name TEXT,  
  Description TEXT,  
  Attack INT,  
  Defence INT,  
  Mana INT,  
  Health INT,  
  Bounty INT,  
  Ability INT,  
  UNIQUE (mID),  
  PRIMARY KEY (mID));
```

```
CREATE TABLE Item (  
  AUTO_INCREMENT,
```

```
  iID INT(11) NOT NULL AUTO_INCREMENT,  
  Name TEXT,  
  Description TEXT,  
  Attack INT,  
  Defence INT,  
  Level INT,  
  UNIQUE (iID),  
  PRIMARY KEY (iID));
```

```
CREATE TABLE Ability (  
  AUTO_INCREMENT,
```

```
  abID INT(11) NOT NULL AUTO_INCREMENT,  
  Name TEXT,  
  Description TEXT,  
  Attack INT,  
  Mgc TEXT,  
  MgcStr INT,  
  Level INT,  
  UNIQUE (abID),  
  PRIMARY KEY (abID));
```

```
CREATE TABLE Instances (  
  AUTO_INCREMENT,
```

```
  inID INT(11) NOT NULL AUTO_INCREMENT,  
  pID INT,  
  mID INT,  
  x FLOAT,  
  y FLOAT,  
  z FLOAT,  
  Respawn INT,  
  UNIQUE (inID),  
  PRIMARY KEY (inID));
```

Step 6:

Populate the database utilizing some mock data. This can be obtained from websites such as Mockaroo (<https://www.mockaroo.com/>). Show proof of this utilizing a screenshot that is included in your report.

Ability:

✓ Showing rows 0 - 11 (12 total, Query took 0.0047 seconds.)

SELECT * FROM `ability`

Step 7:

Run 5 useful SQL queries depending on your application for this database. Provide the screenshot output and include it in your report.

1. *Select current player health from all instances inside the instances table:*

```
SELECT player.Health  
FROM player  
INNER JOIN instances  
ON player.pID = instances.pID;
```

Health
84
88
64

15
55
13
25
78
1
67
43
86
54
47
62
50

2. *Select player health after a 40 damage attack with defence reduction*

```
SELECT player.Health AS 'BEFORE',
SUM(player.Health - 40 + item.Defence) AS 'AFTER',
player.*
FROM player
INNER JOIN account
ON account.pID = player.pID
INNER JOIN item
ON item.iID = player.Item1
WHERE player.Item1 = 12 OR player.Item2 = 12
GROUP BY player.pID
```

+ Options

Norman	110	28	715
Robert	534	28	144
Tim	313	29	203
Robert	206	29	353
Norman	561	30	171

4. *Display the abilities and which monsters use which ability*

```
SELECT Ability.*, Monster.Name
FROM Ability
LEFT JOIN Monster
ON Ability.abID = Monster.Ability;
```

abID	Name	Description	Attack	Mgc	MgcStr	Level	Name

Step 8:

Research how to make the database more efficient for scale and write a two to three paragraph description of what you found when you completed your research (please ensure that you cite credible sources).

Scalability became an issue for databases when cloud architecture became more common, specifically for relational databases. There are multiple techniques that can be used to increase database capacity. The first is to have multiple read replicas of the on different servers, along with a master that accepts both read and write requests. This technique is good for databases that require lots of read requests, and allows for the master to fail since the replicas are exact copies and can replace the master. If there are many write requests, a multi-master technique can be used to allow any client to write data to any available server. This differs from the previous technique such that the replicas are actually masters themselves so the number of reads and writes the system can handle is larger.

Some databases may be so large that just one server will not be able to access and modify data with good performance, so a technique called partitioning may be used instead of multi-masters or replicas. This involves splitting the data up in a logical way. Partitioning may be done horizontally or vertically and allows the database and cache to manage less information at one time. Horizontal partitioning, also known as sharding, is when data is distributed among several servers, and vertical partitioning is when certain data is grouped into frequently accessed and rarely accessed. Another alternative is to forgo relational databases and use a NoSQL system. NoSQL systems are better when it comes to systems that involve massive amounts of rapidly changing data.

Step 9:

One of the most common scripts required for a database job is to export that database to a CSV or a text file. Write a script in any language that will do this, include the code in your submission.

Main.Java

```
import java.sql.*;
import static java.sql.DriverManager.getConnection;

public class Main {

    private static Statement statement;

    public static void main(String[] args) throws Exception {
        Connection connect = getConnection("jdbc:mysql://localhost/projectli", "root", "");
        statement = connect.createStatement();
        export(statement);
    }

    public static void export(Statement statement) throws Exception {

        // ability
        statement.executeQuery("SELECT * FROM ability INTO OUTFILE '/tmp/ability.csv'
        FIELDS TERMINATED BY ',' ENCLOSED BY '\"' LINES TERMINATED BY '\n'");

        // account
        statement.executeQuery("SELECT * FROM account INTO OUTFILE '/tmp/account.csv'
        FIELDS TERMINATED BY ',' ENCLOSED BY '\"' LINES TERMINATED BY '\n'");

        // class
        statement.executeQuery("SELECT * FROM class INTO OUTFILE '/tmp/class.csv' FIELDS
        TERMINATED BY ',' ENCLOSED BY '\"' LINES TERMINATED BY '\n'");

        // instances
        statement.executeQuery("SELECT * FROM instances INTO OUTFILE '/tmp/instances.csv'
        FIELDS TERMINATED BY ',' ENCLOSED BY '\"' LINES TERMINATED BY '\n'");

        // item
        statement.executeQuery("SELECT * FROM item INTO OUTFILE '/tmp/item.csv' FIELDS
        TERMINATED BY ',' ENCLOSED BY '\"' LINES TERMINATED BY '\n'");

        // monster
        statement.executeQuery("SELECT * FROM monster INTO OUTFILE '/tmp/monster.csv'
        FIELDS TERMINATED BY ',' ENCLOSED BY '\"' LINES TERMINATED BY '\n'");

        // player
        statement.executeQuery("SELECT * FROM player INTO OUTFILE '/tmp/player.csv' FIELDS
        TERMINATED BY ',' ENCLOSED BY '\"' LINES TERMINATED BY '\n'");
    }
}
```

Output:

> This PC > Local Disk (C:) > tmp
